PREFACE

The routines described here comprise the SOFA vector/matrix library. Their general appearance and coding style conforms to conventions agreed by the SOFA Board, and their functions, names and algorithms have been ratified by the Board. Procedures for soliciting and agreeing additions to the library are still evolving.

PROGRAMMING LANGUAGES

The SOFA routines are available in two programming languages at present: Fortran 77 and ANSI C.

There is a one-to-one relationship between the two language versions. The naming convention is such that a SOFA routine referred to generically as "EXAMPL" exists as a Fortran subprogram iau_EXAMPL and a C function iauExampl. The calls for the two versions are very similar, with the same arguments in the same order. In a few cases, the C equivalent of a Fortran SUBROUTINE subprogram uses a return value rather than an argument.

GENERAL PRINCIPLES

The library consists mostly of routines which operate on ordinary Cartesian vectors (x,y,z) and 3x3 rotation matrices. However, there is also support for vectors which represent velocity as well as position and vectors which represent rotation instead of position. The vectors which represent both position and velocity may be considered still to have dimensions (3), but to comprise elements each of which is two numbers, representing the value itself and the time derivative. Thus:

* "Position" or "p" vectors (or just plain 3-vectors) have dimension (3) in Fortran and [3] in C.
* "Position/velocity" or "pv" vectors have dimensions (3,2) in Fortran and [2][3] in C.
* "Rotation" or "r" matrices have dimensions (3,3) in Fortran and [3][3] in C. When used for rotation, they are "orthogonal"; the inverse of such a matrix is equal to the transpose. Most of the routines in this library do not assume that r-matrices are necessarily orthogonal and in fact work on any 3x3 matrix.
* "Rotation" or "r" vectors have dimensions (3) in Fortran and [3] in C. Such vectors are a combination of the Euler axis and angle and are convertible to and from r-matrices. The direction is the axis of rotation and the magnitude is the angle of rotation, in radians. Because the amount of rotation can be scaled up and down simply by multiplying the vector by a scalar, r-vectors are useful for representing spins about an axis which is fixed.
* The above rules mean that in terms of memory address, the three velocity components of a pv-vector follow the three position components. Application code is permitted to exploit this and all other knowledge of the internal layouts: that x, y and z appear in that order and are in a right-handed Cartesian coordinate system etc. For example, the cp function (copy a p-vector) can be used to copy the velocity component of a pv-vector (indeed, this is how the CPV routine is coded).
* The routines provided do not completely fill the range of operations that link all the various vector and matrix options, but are confined to functions that are required by other parts of the SOFA software or which are likely to prove useful.
In addition to the vector/matrix routines, the library contains some routines related to spherical angles, including conversions to and from sexagesimal format.

OPERATIONS INVOLVING P-VECTORS AND R-MATRICES

Initialize

ZP        zero p-vector
ZR        initialize r-matrix to null
IR        initialize r-matrix to identity

Copy

CP        copy p-vector
CR        copy r-matrix

Build rotations

RX        rotate r-matrix about x
RY        rotate r-matrix about y
RZ        rotate r-matrix about z

Spherical/Cartesian conversions

S2C       spherical to unit vector
C2S       unit vector to spherical
S2P       spherical to p-vector
P2S       p-vector to spherical

Operations on vectors

PPP       p-vector plus p-vector
PMP       p-vector minus p-vector
PPSP      p-vector plus scaled p-vector
PDP       inner (=scalar=dot) product of two p-vectors
PXP       outer (=vector=cross) product of two p-vectors
PM        modulus of p-vector
PN        normalize p-vector returning modulus
SXP       multiply p-vector by scalar

Operations on matrices

RXR       r-matrix multiply
TR        transpose r-matrix

Matrix-vector products

RXP       product of r-matrix and p-vector
TRXP      product of transpose of r-matrix and p-vector

Separation and position-angle

SEPP      angular separation from p-vectors
SEPS      angular separation from spherical coordinates
PAP       position-angle from p-vectors
PAS       position-angle from spherical coordinates

Rotation vectors

RV2M       r-vector to r-matrix
RM2V       r-matrix to r-vector

OPERATIONS INVOLVING PV-VECTORS
Initialize
  ZPV       zero pv-vector

Copy/extend/extract
  CPV       copy pv-vector
  P2PV      append zero velocity to p-vector
  PV2P      discard velocity component of pv-vector

Spherical/Cartesian conversions
  S2PV      spherical to pv-vector
  PV2S      pv-vector to spherical

Operations on pv-vectors
  PVPPV     pv-vector plus pv-vector
  PVMPV     pv-vector minus pv-vector
  PVXPV     inner (=scalar=dot) product of two pv-vectors
  PVM       modulus of pv-vector
  SXPV      multiply pv-vector by scalar
  S2XPV     multiply pv-vector by two scalars
  PVU       update pv-vector
  PVUP      update pv-vector discarding velocity

Matrix-vector products
  RXPV      product of r-matrix and pv-vector
  TRXPV     product of transpose of r-matrix and pv-vector

OPERATIONS ON ANGLES

Wrap
  ANP       normalize radians to range 0 to 2pi
  ANPM      normalize radians to range -pi to +pi

To sexagesimal
  A2TF      decompose radians into hours, minutes, seconds
  A2AF      decompose radians into degrees, arcminutes, arcseconds
  D2TF      decompose days into hours, minutes, seconds

From sexagesimal
  AF2A      degrees, arcminutes, arcseconds to radians
  TF2A      hours, minutes, seconds to radians
  TF2D      hours, minutes, seconds to days
